BUREAU OF RECLAMATION Central Valley Operations Office 3310 El Camino Avenue, Suite 300 Sacramento, California 95821

IN REPLY REFER TO:

FEB 1 4 2018

CVO-100 PRJ-23.00

VIA ELECTRONIC MAIL AND U.S. MAIL

Ms. Maria Rea Assistant Regional Administrator California Central Valley Area Office 650 Capital Mall, Suite 5-100 Sacramento, Ca 95814

Subject: Transmittal of February 2018 Central Valley Project (CVP) Reservoir Operations Forecasts

Dear Ms. Rea:

As required by the 2009 National Marine Fisheries Service (NMFS) Biological Opinion Reasonable and Prudent Alternatives (RPA) Action I.2.3, please find enclosed a set of CVP operational outlooks and a set of Sacramento River temperature model results for projected operations over the coming spring and summer. It is important to note that these operational outlooks and temperature models do not suggest a certain actual future outcome, but rather the statistical likelihood of an event occurring, including, but not limited to, projected storage and releases as well as temperature performance. Thus, the outlooks do not provide exact end of month storages, flow rates, or projected water temperatures, but general projections that will likely fall within the range of uncertainty based on the different hydrologic runoff conditions between the 90% and 50% hydrology.

The operational outlooks are based on February 1, 2018, hydrologic conditions and a forecast of reservoir inflows assuming both a 90% exceedance hydrology, and a 50% exceedance hydrology. The 90% exceedance hydrology is currently a "Dry" year type under the Sacramento Valley Index. The estimated annual inflow to Shasta Lake is 3.59 million acre-feet (MAF) and the projected end of September storage is 2.2 MAF.

The Sacramento River temperature model runs were completed using the HEC-5Q modeling software, and are also based on February 1 hydrology and a Shasta Lake profile from February 6, 2018. Because this is an early season profile, there is a high degree of uncertainty in the cold water pool volume calculated by the model. Higher confidence will come with the end of April Shasta Lake profile. Based on the model runs, we are currently projecting the capability to meet a 56 degree daily average temperature (DAT) at the Balls Ferry compliance point throughout the season. However, based on past analysis, there is an elevated degree of uncertainty in the September and October timeframe. One factor is that the modeled release temperatures are

cooler than has historically been achieved when all release is through the side gates (lowest gates), especially when there exists a large temperature gradient between the pressure relief gates and the side gates. For this reason, estimated temperatures for September and October in the first table of the attachment are based on a Fall Temperature Index (chart shown in the attachment), illustrating historical performance and indicating some uncertainty in late-season accomplishment of Balls Ferry temperature management at 56 degrees DAT.

The overall projected system operations and hydrologic conditions and the full Federal share of San Luis Reservoir south of the Delta gives us confidence that, even with a conservative

assumption of pumping from the delta, we are able to support the following initial Central Valley Project allocations:

Municipal	& Industrial	February 90% Water Service C Contr	Contracts - Agri	icultural Water Service
	North of Delta M&I	North of Delta Agricultural ¹	South of Delta M&I	South of Delta Agricultural
Allocation	75%	50%	70%	20%

As outlined above, based on the temperature modeling runs illustrating 56 degree performance at Balls Ferry and a 2.2 MAF end of September storage, we believe these conditions are consistent with RPA I.2.3.A, and we request your concurrence with our proposed operations, planning efforts, and allocations. With the uncertainty in September and October temperature performance, we recognize that the possibility exists that we may enter into a condition necessitating the activities under Action I.2.3.B, particularly if the hydrology remains dry in the coming months. Given that potential, please note that the following actions and activities are underway or projected:

- Keswick releases are currently being ramped down to 3,250 cfs; those reductions began on February 12 and due to the required ramping rates, will reach that rate by February 19.
- We believe the attached monthly Keswick release projections can be used during the next one to two months as we further evaluate conditions in coordination with your agency.
 - Though our projection illustrates a 3,250 cfs release projection in March, the ability to hold those releases is dependent on forecasted accretions and creek flows. We plan to further work with NMFS prior to March 1 to develop an understanding of an initial Keswick monthly release schedule. Should changed conditions result in a need to alter releases to meet downstream diversion requirements or Delta outflow, X2, or other legal requirements, Bureau of Reclamation will also consult with NMFS on these real-time changes.

¹ The north of Delta allocations illustrated above are in conformance with Section 4005(e) of P.L. 114-322, the Water Infrastructure Improvements for the Nation Act (WIIN), as well as Reclamation's M&I shortage policy.

• We plan to continue to consult with you monthly or more often as appropriate on the overall outlooks based on updated forecasts.

As noted above, we will be updating the projections of water supply availability and temperature management operations through the coming months as new water supply forecasts become available. We look forward to our continued close coordination as we develop our final Sacramento River temperature management plan for 2018. If you have any questions, please contact Elizabeth Kiteck at 916-979-2197 or Randi Field at 916-979-2066.

Sincerely,

Jeff Rieker Operations Manager

Enc.

Summary of Temperature Results by Month (Monthly Average Temperature °F)

* The HEC5Q model output is displayed above for the months April through August. Based on past analysis, the temperature model does not perform well in late September and October. One factor is that the modeled release temperatures are cooler than has historically been achieved when all release is through the side gates (lowest gates), especially when there's a large temperature gradient between the pressure relief gates (PRG) and the side gates. For the months of September and October estimated temperatures

are provided based on the Fall Temperature Index (graphic below). This relationship is an end of September Lake Shasta Volume less than 56°F and likely downstream temperature performance at Balls Ferry for the early fall months.

Temperature Model Inputs, Assumptions, Limitations and Uncertainty:

1. The latest available profiles for Shasta, Trinity, and Whiskeytown were taken on February 6, February 1, and January 30, respectively. Model results are sensitive to initial reservoir temperature conditions and the model performs best under highly stratified conditions. The February 2018 temperature profile does not yet exhibit conditions for ideal model computations (still nearly isothermal conditions). The model performs well after the reservoir stratifies, typically in late spring. The concern this year is assuming lower than actual inflow temperatures due to low snow/higher than normal air temperature conditions and not capturing the stratification with sufficient detail to project.

2. Guidance on forecasted flows from the creeks (e.g., Cow, Cottonwood, Battle, etc.) between Keswick Dam and Bend Bridge are not available beyond 5 days. Creek flows developed from the historical record that most closely reflects current conditions were used for all model runs. The resulting greater than normal creek flows cause additional warming in the upper Sacramento River during spring.

3. Operation is based on the February 2017 Operation Outlooks (monthly flows, reservoir release, and end-of-month reservoir storage) for the 90%- and 50%-exceedances. Trinity Lake inflows are updated with the CNRFC 90% runoff exceedance for both the 90% and 50% runoff exceedance studies.

4. Although mean daily flows and releases are temperature model inputs, they are based on the mean monthly values from the operation outlooks. Mean daily flow patterns are user defined and are generalized representations. It is important to note that these outlooks do not suggest a certain actual future outcome, but rather the statistical likelihood of an event occurring, including, but not limited to, projected storage and releases. Thus, the outlooks do not provide exact end of month storages or flow rates but general projections that will likely fall within the range of uncertainty based on the different hydrologic runoff conditions between the 90% and 50% runoff exceedance hydrology.

5. Cottonwood Creek flows, Keswick to Bend Bridge local flows, and ACID diversions are mean daily synthesized flows based on the available historical record for a 1922-2002 study period. Inflows were adjusted to a 75% historical exceedance for both the 90% and 50% runoff exceedance studies.

6. Meteorological inputs represent historical (1920 - 2005) monthly mean equilibrium temperature exceedance at 10% and 50% patterned after like months on a 6-hour timestep.

7. Meteorology, as well as the flow volume and pattern, significantly influences reservoir inflow temperatures and downstream tributary temperatures; and consequently, the development of the cold-water pool during winter and early spring.

8. Modified model coefficients more closely represent actual Keswick Dam temperatures. As a result, temperature predictions downstream of Keswick Dam are likely to be warmer than actual. Model re-calibrations efforts are underway.

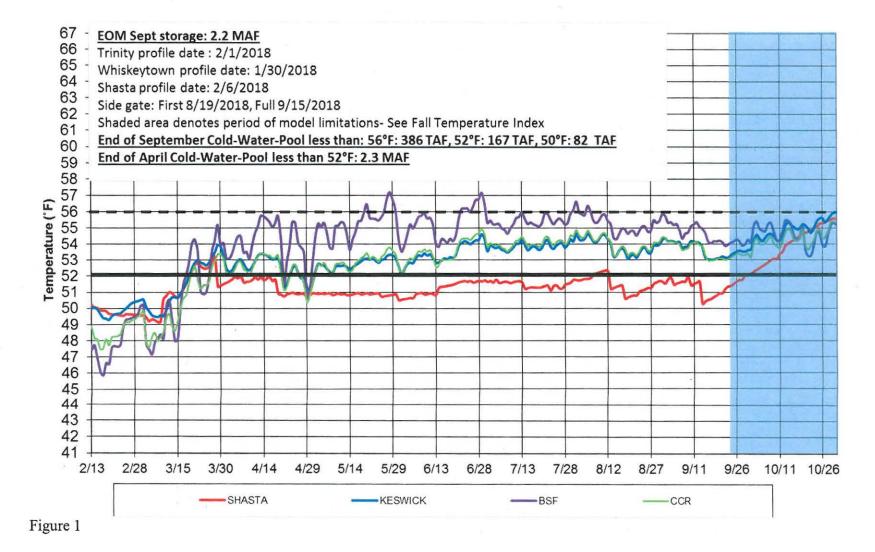

Model Run Date February 13, 2018

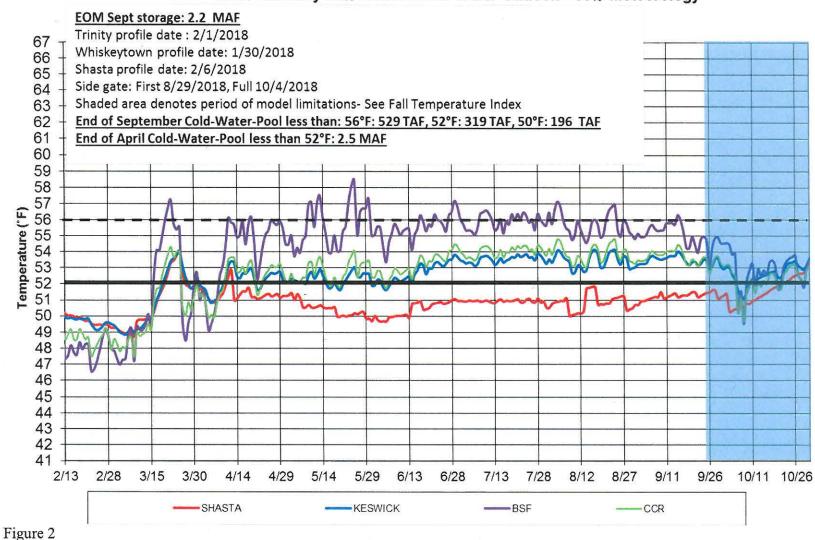

Temperature Analysis Results:

Modeling runs explore Sacramento River compliance performance above Clear Creek confluence and Balls Ferry locations by varying hydrology and meteorology. The temperature results for the Sacramento River between Keswick Dam and Balls Ferry are shown in Figures 1 through 3. The relationship between end-of-September lake volume below 56°F and a Balls Ferry compliance through fall is based on the Figure 5.

Model Run	End of September Cold Water Pool <56°F (TAF)	First Side Gate	Full Side Gates
90% Hydro, 10% Met	386	8/19	9/15
90% Hydro, 50% Met	529	8/29	10/4
50% Hydro, 10% Met	602	9/5	9/24
50% Hydro, 50% Met	707	9/17	10/14

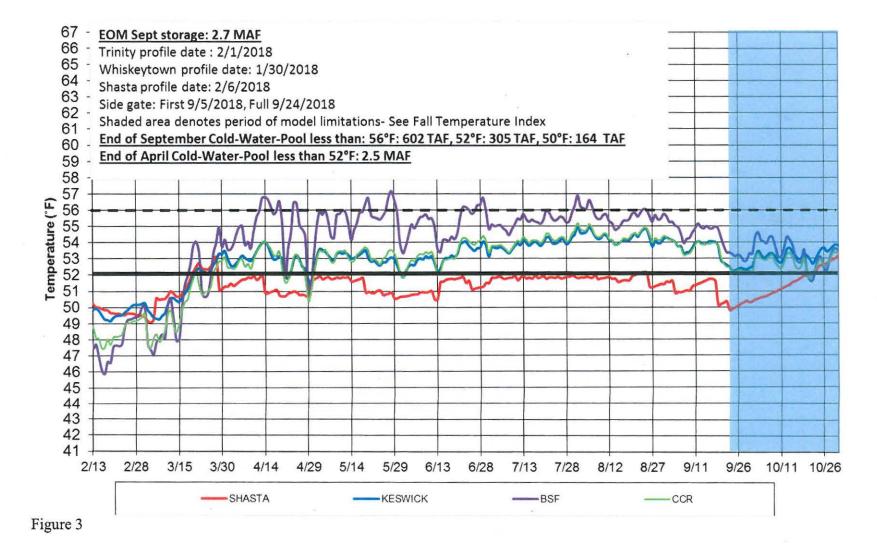

Sacramento River Modeled Temperature 2018 February 90%-Exceedance Water Outlook - 10% Meteorology

Sacramento River Modeled Temperature 2018 February 90%-Exceedance Water Outlook - 50% Meteorology

Sacramento River Modeled Temperature 2018 February 50%-Exceedance Water Outlook - 10% Meteorology

Sacramento River Modeled Temperature 2018 February 50%-Exceedance Water Outlook - 50% Meteorology

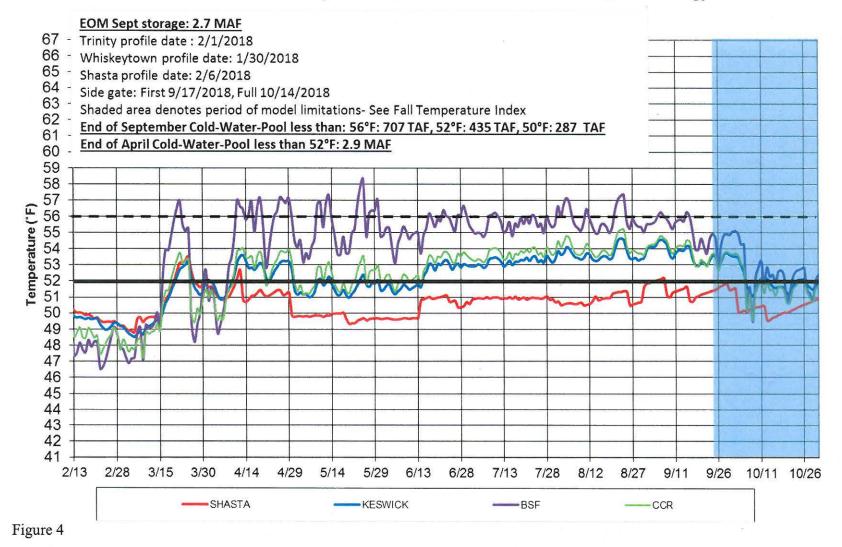

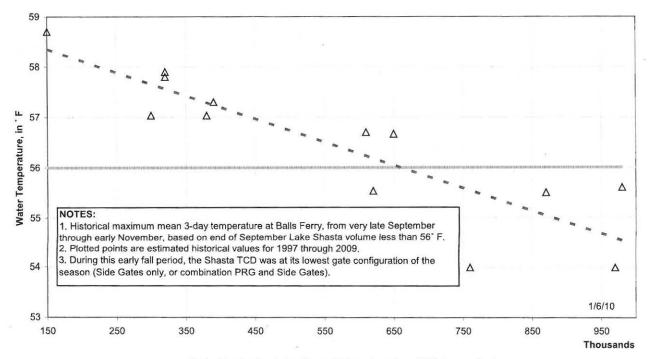

Figure 5 Model Performance and Fall Temperature Index:

1. Based on past analyses, the temperature model does not perform well in late September and October. One factor is that the modeled release temperatures are cooler than has historically been achieved when all release is through the side gates (lowest gates), especially when there's a large temperature gradient between the pressure relief gates (PRG) and the side gates.

2. Based on historical records, the end-of-September Lake Shasta volume below 56°F is a good indicator of fall water temperature in the river reach to Balls Ferry.

3. For river temperatures not to exceed 56 °F downstream to Balls Ferry, the end-of-September lake volume less than 56°F should be greater than about 600 TAF, see chart below:

Sacramento River - Lake Shasta Early Fall Water Temperature at Balls Ferry

End of September Lake Shasta Volume less than 56° F, in acre-feet
